Compiler Design Runtime Environment

Outcome

Different Storage Allocation Strategies.

Outcome ☆ Different Storage Allocation Strategies.

Memory Layout:

Static / Global Variable Stack Heap Machine Code Memory Layout:

Storage Allocation Strategies:

1. **Static:**
 - i. Allocation is done at Compile time.
 - ii. Bindings do not change at Run time.
 - iii. One activation record per procedure.

A light gray rectangular box representing a program, containing the following text:
 $f_1()$
 $f_2()$
 $f_3()$
 $f_4()$
 $f_5()$

Program

$f_1()$
$f_2()$
$f_3()$
$f_4()$
$f_5()$

Static Allocation

Storage Allocation Strategies: 1. Static: i. Allocation is done at Compile time. ii. Bindings do not change at Run time. iii. One activation record per procedure. $f_1()$ $f_2()$ $f_3()$ $f_4()$ $f_5()$ Static Allocation $f_1()$ $f_2()$ $f_3()$ $f_4()$ $f_5()$ Program

Storage Allocation Strategies:

1. **Static:**
 - i. Allocation is done at Compile time.
 - ii. Bindings do not change at Run time.
 - iii. One activation record per procedure.
- **Cons:**
 - i. Recursion is not supported.
 - ii. Size of data objects must be known at Compile time.
 - iii. Data Structures cannot be created dynamically.
- **Pro:** The element which is provided with the static allocation gets the lifetime as same as the process itself.

† **Note:** Global Arrays are static by default.

Storage Allocation Strategies: 1. Static: i. Allocation is done at Compile time. ii. Bindings do not change at Run time. iii. One activation record per procedure. • Cons: i. Recursion is not supported. ii. Size of data objects must be known at Compile time. iii. Data Structures cannot be created dynamically. • Pro: The element which is provided with the static allocation gets the lifetime as same as the process itself. Note: Global Arrays are static by default.

Storage Allocation Strategies:

2. **Stack:** Whenever a new activation begins, the activation record is pushed onto the stack and whenever activation ends, the activation record is popped off.

Storage Allocation Strategies: 2. Stack: Whenever a new activation begins, the activation record is pushed onto the stack and whenever activation ends, the activation record is popped off. `f1(){f2(){f3()Stackf2(){f3()}}f3(){}f1(){f2(){f3()}}}`

Storage Allocation Strategies:

2. **Stack:** Whenever a new activation begins, the activation record is pushed onto the stack and whenever activation ends, the activation record is popped off.

- **Con:** Local variables cannot be retrieved once activation ends.
- **Pro:** Recursion is supported.

Storage Allocation Strategies: Whenever a new activation begins, the activation record is pushed onto the stack and whenever activation ends, the activation record is popped off. ● Con: Local variables cannot be retrieved once activation ends. ● Pro: Recursion is supported. 2. Stack:

Storage Allocation Strategies:

3. **Heap:** Allocation and deallocation can be done any order.

- **Con:** Heap management is an overhead.

📌 **Note:** In C programming, **First Fit** is used.

Storage Allocation Strategies: Allocation and deallocation can be done any order. • Con: Heap management is an overhead. 3. Heap: Process Machine Code Hole Note: In C programming, First Fit is used.

Storage Allocation Strategies – Summary:

1. Permanent lifetime in case of static allocation.
2. Nested lifetime in case of stack allocation.
3. Arbitrary lifetime in case of heap allocation.

Storage Allocation Strategies - Summary: 1. Permanent lifetime in case of static allocation. 2. Nested lifetime in case of stack allocation. 3. Arbitrary lifetime in case of heap allocation. Static / Global Variable Stack Heap Machine Code

Compiler – Internal Architecture

Lexical Analysis Syntax Analysis Semantic Analysis Intermediate Code Generation Code Optimization Target Code Generation Analysis Phase Synthesis Phase Compiler - Internal Architecture

Objective of Code Optimization:

1. The optimization must be **correct** and **must not change the meaning of the program**.
2. The compilation time must be kept **reasonable**.
3. The optimization process **should not delay** the overall compiling process.
4. Optimization should increase the **speed** and **performance** of the program.

Objective of Code Optimization: 1. The optimization must be correct and must not change the meaning of the program. 2. The compilation time must be kept reasonable. 3. The optimization process should not delay the overall compiling process. 4. Optimization should increase the

speed and performance of the program.

Purpose of Code Optimization:

1. It is used to **reduce** the consumed memory space.
2. It is used to **increase** the compilation speed.
3. An optimized code facilitates **re-usability**.

Types of Code Optimization:

- **Machine Independent:**
 - Improves the **intermediate code**.
- **Machine Dependent:**
 - It involves **CPU registers** and may have **absolute memory references** rather than relative references.
 - It is performed **after the target code has been generated**.

Purpose of Code Optimization: 1. It is used to reduce the consumed memory space. 2. It is used to increase the compilation speed. 3. An optimized code facilitates re-usability. Types of Code Optimization: ● Machine Independent: - Improves the intermediate code. ● Machine Dependent: - It involves CPU registers and may have absolute memory references rather than relative references. - It is performed after the target code has been generated.

Types of Code Optimization:

Machine Independent Optimizations

1. Loop Optimizations

Machine Dependent Optimizations

Loop Optimization:

```
for(int i=0;i<10;i++)  
{  
    a = i*2;  
}  
for(int j=0;j<10;j++)  
{  
    b = j+3;  
}
```

```
for(int i=0;i<10;i++)  
{  
    a = i*2;  
    b = i+3;  
}
```

Loop Optimization: `for(int i=0;i<10;i++){ a = i*2;} for(int j=0;j<10;j++){ b = j+3;} for(int i=0;i<10;i++){ a = i*2;b = i+3;}`

Types of Code Optimization:

How to find the Basic Blocks?

-- Find the **Leader**.

How to find the Basic Blocks?

-- Find the **Leader**.

Identifying the Leader:

1. **First statement** is a leader.
2. Statement that is the **target** of a conditional or unconditional GOTO is a leader.
3. Statement that **immediately follows** a conditional or unconditional GOTO is a leader.

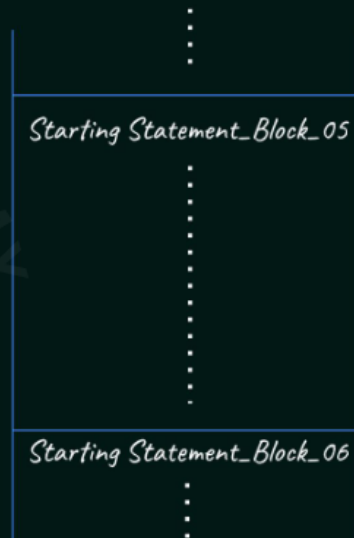

Illustration – Producing PFG:

HLL code:

```
fact(a){
  int f = 1;
  for(i=2;i<=a;i++)
    f = f * i;
}
```

TAC:

```
1. f = 1
2. i = 2
3. if(i<=a) GOTO 9
4. t1 = f * i
5. f = t1
6. t2 = i + 1
7. i = t2
8. GOTO 3
9. GOTO <Calling Program>
```

Compiler Design

Loop Optimization Techniques

Outcome

- ☆ Different types of Loop Optimization Techniques.

Outcome ☆ Different types of Loop Optimization Techniques.

Loop Optimization Technique – Code Motion:

- The **number of statements** within the loop is **reduced**.
- Also known as **Frequency reduction**.

```
while(i<1000)
{
    a = (sin(x)/cos(x)) * i;
    i++;
}

t = sin(x)/cos(x);
while(i<1000)
{
    a = t * i;
    i++;
}
```

📌 **Note:** Moving the expression with computation outside, is a.k.a. **Loop Invariant Method**.

Loop Optimization Technique - Code Motion: • The number of statements within the loop is reduced. • Also known as Frequency reduction. while(i<1000){a = (sin(x)/cos(x)) * i;i++;}t = sin(x)/cos(x);Note:Moving the expression with computation outside, is a.k.a. Loop Invariant Method.while(i<1000){a = t * i;i++;}

Loop Optimization Technique – Loop Unrolling:

- If possible, **eliminate** the entire loop.

```
for(int i=0;i<5;i++)  
{  
    printf("Hello");  
}  
→  
printf("Hello");  
printf("Hello");  
printf("Hello");  
printf("Hello");  
printf("Hello");
```

Loop Optimization Technique - Loop Unrolling: • If possible, eliminate the entire loop.

```
for(int i=0;i<5;i++){  
    printf("Hello");  
}printf("Hello");printf("Hello");printf("Hello");printf("Hello");printf("Hello");
```

Loop Optimization Technique – Loop Jamming:

- **Combine** the loop bodies.
- Also known as **Loop Fusion**.

```
for(int i=0;i<10;i++)  
{  
    a = i*2;  
}  
for(int j=0;j<10;j++)  
{  
    b = j+3;  
}  
→  
for(int i=0;i<10;i++)  
{  
    a = i*2;  
    b = i+3;  
}
```

⚠ **Note:** The opposite transformation is called **Loop fission** or **Loop distribution**.

Loop Optimization Technique - Loop Jamming: • Combine the loop bodies. • Also known as Loop Fusion.

```
for(int i=0;i<10;i++){ a = i*2;} for(int j=0;j<10;j++){ b = j+3;}for(int i=0;i<10;i++){ a = i*2;b = i+3;}Note:The opposite transformation is called Loop fission or Loop distribution.
```

Loop Optimization Technique – Loop Unswitching:

- It **lifts** conditions out of loops, creating two loops.

```
for(i=0;i<100;++i)
{
    if(c)
    {
        f();
    }
    else
    {
        g();
    }
}

if(c)
{
    for(i=0;i<100;++i)
        f();
}
else
{
    for(i=0;i<100;++i)
        g();
}
```

† **Note:** Also known as **Loop splitting**.

Loop Optimization Technique - Loop Unswitching: • It lifts conditions out of loops, creating two loops. `for(i=0;i<100;++i){ if(c){f(); } else { g(); }}if(c) {for(i=0;i<100;++i) f();} else {for(i=0;i<100;++i) g();}` **Note:** Also known as Loop splitting.

Loop Optimization Technique – Loop Peeling:

- Here problematic iteration is **resolved separately** before entering the loop.

```
for(i=0;i<10;i++)
{
    if(i==0)
        a[i] = . . .
    else
        b[i] = . . .
}

a[0] = . . .
for(i=1;i<10;i++)
{
    b[i] = . . .
}
```

Loop Optimization Technique - Loop Peeling: • Here problematic iteration is resolved separately before entering the loop. `for(i=0;i<10;i++){if(i==0)a[i] = . . .else b[i] = . . .}a[0] = . . .for(i=1;i<10;i++){b[i] = . . .}`

2. Instruction Scheduling
3. Peephole Optimizations
a. Redundant LOAD and STORE
b. Flow Control Optimizations
c. Use of Machine Idioms
1. Loop Optimizations
2. Constant Folding
3. Constant Propagation
4. Operator Strength Reduction
5. Dead Code Elimination
6. Common Subexpression Elimination
7. Algebraic Simplification

Constant Folding:

- Evaluation of expressions at compile-time.
- Applicable to the operands which are known to be constant.

$a = 10 * 5 + 6 - b;$ \rightarrow $a = 56 - b;$

Constant Folding: • Evaluation of expressions at compile-time. • Applicable to the operands which are known to be constant. $a = 10 * 5 + 6 - b$; $a = 56 - b$;

Constant Propagation:

- If a variable is assigned a **constant value**, then subsequent uses of that variable can be replaced by the constant as long as no intervening assignment **has changed** the value of the variable.

1. $a = 13.7$ $b = a/4.5$	→	$a/4.5$ as $13.7/4.5$
2. $j = 1$ $\text{if}(j) \text{ GOTO } L$	→	$\text{GOTO } L$

Constant Propagation: • If a variable is assigned a constant value, then subsequent uses of that variable can be replaced by the constant as long as no intervening assignment has changed the value of the variable. 1. $a = 13.7$ $b = a/4.5$ 2. $j = 1$ $\text{if}(j) \text{ GOTO } L$ $a/4.5$ as $13.7/4.5$ $\text{GOTO } L$

Operator Strength Reduction:

- It replaces an operator by a **less expensive** one.

$b = a * 2$	→	$b = a \ll 1$
-------------	---	---------------

Operator Strength Reduction: • It replaces an operator by a less expensive one. $b = a * 2b = a \ll 1$

Dead Code Elimination:

- If an instruction's result is never used, the instruction is considered **dead** and can be **removed** from the instruction stream.

~~$t_1 = t_2 \times t_3$~~

- If t_1 holds the **result of a function call**, we **cannot eliminate** the instruction.

$t_1 = t_2 \times t_3$ Dead Code Elimination: • If an instruction's result is never used, the instruction is considered dead and can be removed from the instruction stream. • If t_1 holds the result of a function call, we cannot eliminate the instruction.

Common Subexpression Elimination:

- Two operations are common if they produce **the same result**. In such a case, it is likely more efficient to **compute the result once** and **reference it the second time** rather than re-evaluate it.

$A = B + C$
 $D = 2 + B + 3 + C$

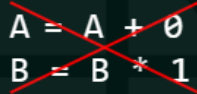

→

$A = B + C$
 $D = 2 + 3 + A$

$A = B + CD = 2 + B + 3 + C$
Common Subexpression Elimination: • Two operations are common if they produce the same result. In such a case, it is likely more efficient to compute the result once and reference it the second time rather than re-evaluate it. $A = B + CD = 2 + 3 + A$

Algebraic Simplification:

- Simplifications use **algebraic properties** or particular operator-operand combinations to simplify expressions.
- These optimizations can **remove** useless instructions entirely via algebraic identities.

$$\begin{array}{l} A = A + 0 \\ B = B * 1 \end{array}$$

• Simplifications use algebraic properties or particular operator-operand combinations to simplify expressions. • These optimizations can remove useless instructions entirely via algebraic identities. $A = A + 0$ $B = B * 1$
Algebraic Simplification:

Liveness Analysis:

What is Liveness?

A variable is **live** if its value will be used before it gets overwritten.

Why is it important?

- **Register allocation:** It helps in deciding which variables **to keep in registers** and which **to store in memory** to optimize performance.
- **Dead code elimination:** It can be used to **identify and remove code** that computes values that are never used.
- **Code scheduling:** It's used to reorder instructions **to minimize stalls** and **improve** instruction-level **parallelism**.

Liveness Analysis: What is Liveness? A variable is live if its value will be used before it gets overwritten. Why is it important? • Code scheduling: • Register allocation: It helps in deciding which variables to keep in registers and which to store in memory to optimize performance. • Dead code elimination: It can be used to identify and remove code that computes values that are never used. It's used to reorder instructions to minimize stalls and improve instruction-level parallelism.

Liveness Analysis – Algorithm:

 **Input:** Program Flow Graph

 **Output:** Liveness Information

- IN[B] (Set of variables that are live **at the beginning** of the Block)
- OUT[B] (Set of variables that are live **after** the Block)
- DEF/KILL[B] (Set of variables that are **defined/killed** in the Block)
- USE/GEN[B] (Set of variables that are **used/generated** in the Block)

Liveness Analysis - Algorithm: Program Flow Graph
 Input: Liveness Information
 Output: -- IN[B] -- OUT[B] -- DEF/KILL[B] -- USE/GEN[B] (Set of variables that are used/generated in the Block) (Set of variables that are live at the beginning of the Block) (Set of variables that are

live after the Block)(Set of variables that are defined/killed in the Block)

Liveness Analysis – Algorithm:

1. **Initialization:** IN and OUT sets are initially empty.
2. **Worklist Initialization:** Create a worklist containing all the Basic Blocks of the CFG.
3. **Iterative Dataflow Analysis:** While the worklist is not empty, perform the following steps for each basic block:
 - Calculate $IN[B] = USE[B] \cup (OUT[B] - DEF[B])$
 - Calculate $OUT[B] = \cup IN[S]$
4. **Final Liveness Information:** After the analysis has converged, the 'IN' sets represent the live variables at the entry points of each block.

Liveness Analysis - Algorithm: IN and OUT sets are initially empty. 1. Initialization: Create a worklist containing all the Basic Blocks of the CFG. 2. Worklist Initialization: 4. Final Liveness Information: After the analysis has converged, the 'IN' sets represent the live variables at the entry points of each block. 3. Iterative Dataflow Analysis: While the worklist is not empty, perform the following steps for each basic block: • Calculate $IN[B] = USE[B] \cup (OUT[B] - DEF[B])$ • Calculate $OUT[B] = \cup IN[S]$

Q: A variable x is said to be live at a statement S_i in a program if the following three conditions hold simultaneously:

1. There exists a statement S_j that uses x
2. There is a path from S_i to S_j in the flow graph corresponding to the program
3. The path has no intervening assignment to x including at S_i and S_j

The variables which are live both at the statement in basic block 2 and at the statement in basic block 3 of the above control flow graph are

- a. p, s, u
- b. r, s, u
- c. r, u
- d. q, v
